

# OBLIQUE CASE AND INDO-EUROPEAN ERGATIVITY SPLITS<sup>1</sup>

M. RITA MANZINI, LEONARDO M. SAVOIA

**Abstract.** We argue that the fundamental oblique case of natural languages (the genitive/dative) corresponds to an elementary inclusion or part-whole predicate, whose internal argument (the whole, or possessor) is the DP which the case embeds, while its external argument is a DP (the part or possessum) coinciding either with the head of a genitive construction or with the theme of a ditransitive verb. In some languages, the all purposes oblique (as in Kurdish) or a specialized oblique, i.e. the ergative (as in Punjabi), lexicalizes the (transitive) subject of perfect sentences. We propose that (in these languages) perfect predicates correspond to a VP projection; external arguments are introduced by means of an oblique case, saying that the event is ‘included by’ (cf. ‘located at’) the argument. A more complex organization is found with imperfective/progressive predicates, where a head Asp projects a functional layer and can introduce the external argument, determining nominative type agreement.

**Keywords:** oblique case, dative, genitive, ergative, ergativity split.

## 1. INTRODUCTION: OBLIQUE CASE

We will begin by discussing the notion of case, in particular the indirect object case; our aim is to make the content of oblique case precise, trying to clarify its relation with the syntaxes based on the so-called split of ergativity. In this section, we briefly address the question of dative and genitive obliques in relation to Romanian, the only Romance language with overt case on DPs. In section 2, we address the issue of ergativity in connection with Punjabi and Kurdish, i.e. languages which present a perfectivity-based split between nominative and ergative alignments, allowing a comparison between nominative alignments in the imperfective and ergative alignment in the perfect. Based on our

<sup>1</sup> M. Rita Manzini, Università di Firenze, rmanzini@unifi.it, Leonardo M. Savoia, Università di Firenze, lsavoia@unifi.it. Data of Punjabi are transcribed in a broad IPA from the (Doabi) variety spoken in Hoshiarpur (India). We thank Miss Rajvir Kaur and her family for their collaboration. Kurdish data are obtained through interviews with Northern Iraqi native speakers of the Bahdini variety of Kurmanji. This research benefitted from PRIN 2012 funds, granted by the Italian MIUR. More detailed reports have been published by the authors on oblique cases in Latin and Romance (Manzini and Savoia 2011a, 2014a), on Albanian (Manzini and Savoia (2011a, 2011b), on ergativity splits in Punjabi and Kurdish (Manzini *et al.* 2015). The present article reflects in a particularly close way the conceptual path that has led us from the investigation of complement obliques to that of subject obliques, in the shape of ergative subjects.

conclusions in the preceding sections, in sections 3–4 we will argue that ergative is a bona fide oblique, and we will further provide a characterization for it that allows us to understand the common syncretism with ‘possessor’ cases (dative, genitive).

### 1.1. Genitive and dative

Within the minimalist approach (Chomsky 1995, 2001, 2013), properties such as gender (nominal class), number and person, which are intrinsically associated with nominal constituents, are features. However relations, for instance theta-roles, are not features, but correspond to syntactic configurations. From this perspective, it is potentially problematic to find that case is treated as a feature, i.e. as nominal class or as number rather than as theta-roles. The fact that case is the only feature in Chomsky (1995) which is radically uninterpretable (i.e. which does not have an interpretable counterpart) is a reflex of the deeper difficulty in reconciling the traditionally relational core of this notion with its feature status. The solution at which Chomsky (2001) arrives is that the real underlying relation between case assigner and case assignee is an agreement relation, involving phi-features; case is but a reflex of this relation which appears on nominal constituents.

Chomsky’s proposal only directly covers nominative and accusative (reflexes of phi-feature checking on T and *v* respectively). If we ask ourselves how Chomsky’s approach could be applied to obliques, the Applicative literature comes naturally to mind (Pylkkänen 2008; Cuervo 2003, on Romance). According to this literature a functional head Appl checks the descriptive dative. We could therefore say that dative is but the reflex of phi-feature agreement between Appl and a DP.

Yet the morphosyntactic reality of Indo-European languages is that cases are uniquely represented in the morphology of nouns (and nominal constituents) and not on the verb or verbal constituents. Therefore, at least for obliques we follow a different tradition, equally represented in formal approaches (cf. originally Fillmore 1968) – namely that they are inflectional counterparts of Ps – in other words elementary predicates mediating the attachment of DPs to the eventive core of the sentence. For example, in a French expression like *le livre de Jean* ‘the book of Jean’ the preposition *de* can be taken to introduce the ‘possession’ relation, between *Jean* (the possessor) and ‘the book’. Similarly, in the German expression *Johann-s Buch* ‘John’s book’, we take the *-s* case ending to realize the ‘possession’ relation as a morphological inflection. This does not contradict Chomsky’s (2001) conclusion as to the incompatibility of feature status with relational content – rather it derives different consequences from it, namely that (oblique) case is not a feature. In fact, though we reject the agreement for obliques, reduction of case to agreement, the present approach can be seen as an implementation of deeper insight of Chomsky (2001) that case is not a primitive category.

Our view of oblique is perhaps most intuitively apprehended starting from the syncretism between genitive and dative, widely attested in natural languages, including Romanian. Romanian displays a two case declension, contrasting nominative/ accusative and oblique; the latter covers sentential (dative) and nominal (genitive) embeddings. In (1a) we exemplify the dative plural with an embedding under ‘give’. In (1b) we show that the forms of the dative are identical to those of the genitive, illustrated by an embedding under N. Since the syncretism of genitive and dative is ‘absolute’ (in the sense of Calabrese 2008), one ordinarily speaks of a single oblique case.

- (1) a. (I) I-am dat băieṭ-i-l-or / fet-e-l-or  
 him it.I.have given boy-mpl-def-obl/ girl-fpl-def-obl  
 ‘I gave it to the boys/ girls.’
- b. pahar-ul băieṭ-i-l-or / fet-e-l-or  
 glass-msg.def boy-mpl-def-obl/ girl-fpl-def-obl  
 ‘the glass of the boys/ girls’ *Romanian*

The oblique forms in (1) have three separate layers of inflection. The leftmost layer is the nominal class morphology *-i* for the masculine plural and *-e* for the feminine plural. The second layer is an *-l* definiteness specification; though Romanian is often described as a language with post-nominal articles, here we assume that the definiteness morphology is generated as an inflection within the noun (cf. Dimitrova-Vulchanova and Giusti 1998). Finally the *-or* ending lexicalizes oblique (dative/genitive) case. The direct case form – nominative/ accusative – in (2) doubles the gender and plural number morphemes *-i/ -e* on the right of the verb base (masculine) or on either side of the *-l*- definiteness morphology (feminine). In other words, it lacks any specialized formative for case, as in (2).

- (2) Au venit/ am văzut băieṭ-i-i/ fet-e-l-e  
 have come/ I.have seen boy-mpl-mpl/ girls-fpl-def-fpl  
 ‘There came/ I saw the boys/ girls’ *Romanian*

In minimalist approaches, Romanian *-or* in (1) would be the lexicalization of an uninterpretable feature, which is either checked against a similar uninterpretable feature of the head of the construct (verb or noun), as in Chomsky (1995), or is checked as part of an Agree process (Chomsky 2001, 2008). The conditional is necessary here to the extent that Chomsky only explicitly discusses direct cases. In present terms, *-or* in (1) is the inflectional equivalent of the prepositions *to* or *of*, i.e. a predicate introducing a ‘possession’ relation between the argument it selects and another argument.

An idea put forth in very similar terms by various strands of literature is that possession is a surface manifestation of the more elementary part-whole relation. Thus Manzini and Savoia (2007) propose that the Romance clitic *ne* (syncretic in some varieties between genitive and dative) introduces reference to a set which is a ‘superset-of’ some other argument of the sentence (the internal argument, cf. Burzio 1986). Belvin and den Dikken (1997: 170) define the relation introduced by ‘have’ as ‘zonal inclusion’ in the following terms: “the ‘meaning’ of have ... denotes a special kind of inclusion relation ... dubbed ‘zonal inclusion’ ... Entities have various zones associated with them, such that an object or eventuality may be included in a zone associated with an entity without being physically contained in that entity... The type of zones which may be associated with an entity will vary with the entity”. Boneh and Sichel (2010) take the Part-Whole relation to be the conceptual core of partitives (*three of them*) and of inalienable possession (*John’s nose*).

Let us consider for instance the dative. The line of analysis of ditransitive verbs initiated by Kayne (1984) is characterized by the assumption that verbs like ‘give’ take a predication as their complement; the content of this predication is a possession relation between the accusative direct object (the possessum) and the dative (the possessor)(cf. Pesetsky 1995, Beck and Johnson 2004, Harley 2002). We take ‘inclusion’ (part-whole) to

be the primitive content of the ‘to’ preposition; we take oblique case, for instance in Romanian (1a), to have the same content. We notate inclusion with  $\subseteq$ , though as indicated by the discussion that precedes, the inclusion relation is to be construed not mathematically but as a looser zonal inclusion one.

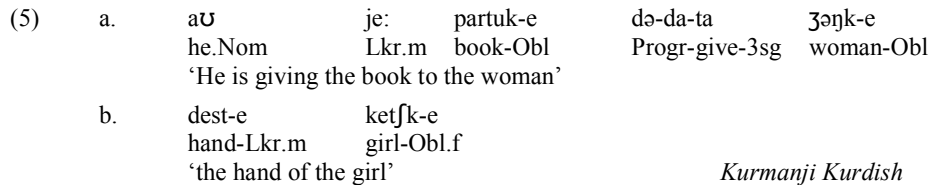

In (3) we provide a structure for Romanian (1a), where the  $\subseteq$  content is associated with the case ending *-or*. It has often been suggested that case ought to be recognized as a category unto itself, namely K; on the contrary Manzini and Savoia (2011b), who introduce the  $\subseteq$  notation suggest that Q, given its relational core is closest to case morphology. We simply label Romanian *-or* as  $\subseteq$  in (3). The  $\subseteq$  element takes as its complement its sister DP *băieții/-fetel-* ‘the boys/the girls’ and as its external argument the sister DP to its projection, i.e. *paharul* ‘the glass’, and says that ‘the glass’ is ‘zonally included’ by ‘the boys’ or ‘the girls’ (it is in their material possession, or in their vicinity, etc.).

The same oblique case illustrated in a sentential embedding (‘dative’) in (3), is also found in nominal embeddings (‘genitive’), as in (1b). Applying the same analysis as in (3), we obtain structure (4) for Romanian (1b). The interpretation is also the same, namely that ‘the glass’ is in the domain of inclusion of the possessor ‘the boys’.

Similarly in Kurmanji Kurdish the case inflections *-i* for masculine singular, *-e* for feminine singular and *-a* for plural, traditionally characterized as obliques can lexicalize goal (thematic) datives, as in (5a), and possessor genitives in the DP, as in (5b).<sup>2</sup>

The present approach, that unifies ‘genitive’ and ‘dative’ is not invalidated by

<sup>2</sup> Bahdini Kurmanji has a system of ‘tense ezafes’ (Haig 2011) in the non-perfect tenses, glossed ‘Linker’ (Lkr), which agree with the nominative subject (cf. Franco *et al.* 2015). An ezafe, i.e. a linker, is also present in (5b), agreeing with the head noun.

languages with specialized genitive and dative. In English itself *of* specializes for nominal embedding and *to* for sentential embedding. Simply the oblique content ( $\sqsubseteq$ ) is lexicalized as *of* or as *to* depending on whether it is dominated by NP or VP. An example of distinct genitive and dative cases is provided by Punjabi, where we identify the *-nu* suffix with the dative in that it lexicalizes the second internal argument of ditransitives, i.e. the goal argument, as in (6a). The genitive in turn is realized as *d-* (on lexical nouns), as in (6b).<sup>3</sup>

- (6) a. mε:                      ti-nnu                      kita:b                      din-d-i (a)  
 I.Abs(f)                      you-Obl book.Abs.fsg                      give.Progr.fsg                      be.Pres  
 ‘I giveyou the book’
- b. muṛḍ-e-d-i-i-ā                      kita:b/ kitabb-a  
 boy-Obl.msg-Gen-fsg/-fpl                      book.Abs.fsg/ book-Abs.fpl  
 ‘the book/the books of the boy’                      Punjabi

In (6a), the *-nu* dative case introduces a possessor/inclusion relation ( $\sqsubseteq$ ), taking as its internal argument the DP to which it attaches, ‘you’, and as its external argument the local DP ‘book’. The genitive, as in (6b), which is canonically taken to correspond to possession, is also a candidate for ( $\sqsubseteq$ ) content in present terms. We propose that the two different lexicalizations *-nu* and *-de* for the same ( $\sqsubseteq$ ) category correspond to a contextual sensitivity of ( $\sqsubseteq$ ) in Punjabi. Thus ( $\sqsubseteq$ ) is lexicalized as *-nu* when attached to sentential projections (‘dative’), as in (7a), while it is lexicalized as *-de* when it is attached to nominal categories (‘genitive’), as in (7b).

- (7) a. [VP [PredP ti[ $\sqsubseteq$ ]nnu] kita:b] dindi]  
 b. [DP[ $\sqsubseteq$ ]muṛḍe [ $\sqsubseteq$ ] di]] kita:b]                      Punjabi

Before concluding this paragraph, let us briefly consider the status of direct case in Romanian, coinciding with the simple morphology of gender and number (nominal class properties, N), as illustrated in (2). Manzini and Savoia (2007) adopt the analysis in Higginbotham (1985) in proposing that nominal bases are predicates, whose obligatory argument is ultimately saturated by Definiteness and other quantifiers. The nominal (gender/number) morphology overtly visible in Romance languages provides a descriptive content for the argument. Thus, in (8) the lexical base ‘*fet*’ denotes the property ‘girl’, and the nominal class (feminine)/ plural morphology *-e* and definiteness morphology *-l-* provide a descriptive content and quantificational closure for the argument of the predicative base.

- (8)
- 
- Romanian

<sup>3</sup> The genitive also bears an inflection agreeing with the head noun.

sketched for Romanian (8), namely that the number and nominal class properties of the so-called absolutive/nominative DPs in (9)/(10) are sufficient to lexicalize the direct arguments of the verb (the internal argument, i.e. sister of V, and the external argument, i.e. Spec, vP). For descriptive purposes we will keep referring to the nominative in Kurdish, while following Bayley (1904), we will speak of the absolute form of the noun rather than of absolutive case in Punjabi<sup>4</sup>.

The research question we want to ask is what relation there is, if any, between the subject oblique in (9a) and the complement obliques that we have studied in section 1.1. We are prompted to ask this question by the existence of an important stream of (formal and historico-typological) literature which connects ‘ergative’ structure with ‘possession’ structures. Montaut (2004: 39) quotes Benveniste’s (1966: 176–186) conclusion that “the Old Persian structure ... is intrinsically possessive in its meaning, and is analogical with the periphrastic perfects in Latin (*mihi id factum*, me-DAT this done)”. In other words, the external argument is treated as the possessor of a state – the relation of the external argument to the predicate is formally identical to that found with nominal predicates. In the words of Johns (1992: 68), “similarities in case and agreement between transitive clauses and possessive phrases is a long-standing issue in Eskimo linguistics... The first of these similarities is that the case assigned to the specifier (possessor) of a possessed noun is the relative case, the same case that is assigned to the actor in the transitive construction”.

Before we can come back to our proposal on the matter we need however to investigate in some detail the aspectual split – on which the presence of oblique/ergative subjects depends.

## 2. THE ASPECTUAL SPLIT

Recent generative work has explored the idea that ergative alignments correspond to a somewhat more elementary organization of the predicate, or of the sentence than nominative alignments. For Baker and Atlamaz (2013), the perfect is passive-like and differs from the imperfective in that it involves a non-phasal v. Laka (2006) proposes that nominative alignment implies a biclausal structure in Basque. Coon (2013) has a similar analysis of Chol (Mayan). In Coon’s analysis, both perfectives and imperfectives have the same underlying predicate structure. Imperfectives however are embedded under an aspectual auxiliary, determining the switch in alignment. Based on Georgian, Nash (2014) adopts a two-layered structuring of both perfective and imperfective predicates, namely v-V. Aorist aspect is characterized just by the v-V structure and all arguments are introduced within this structure. By contrast, imperfective aspect is introduced by a specialized aspectual node Event, which is also responsible for licensing the external argument of transitives; in this respect Nash thinks of the Event node as akin to Voice in the sense of Harley (2013). Nash concludes that: “the deficient perfectivity of sentences in Georgian aorist... is rather a result of the absence of any Aspect category in the clausal functional structure”. In the perfect “the event is just named without referring to the specifics of its internal temporal organisation as if it were “nominalised” in some sorts”. In what follows, we will provide a different implementation of the same basic idea – which in our view has certain empirical and theoretical advantages.

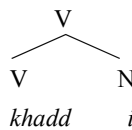

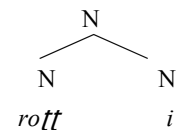

<sup>4</sup> A rejection of abstract case has precedents in generative grammar, specifically in Marantz (1991) who proposes a morphological algorithm for case.

## 2.1. The perfect

In Punjabi (Bhatia 2000), the perfect verb is a participial form, bearing number and nominal class (i.e. gender) inflections; this participial form may be embedded under a ‘be’ auxiliary, which is however optional. In the transitive sentences in (10a) above or in (11), the internal argument is in the absolute form, the external argument bears the ergative case, and the perfect agrees with the internal argument.

- (11) o-ne                      roṭṭ-i                      khadd-i                      si  
 s/he-Erg                      bread-Abs.fsg                      eat.Perf-fsg                      be.Past  
 ‘S/he ate the/some bread’ Punjabi

In (11), the noun *roṭṭ-i* ‘(the) bread’ consists of the predicative base *roṭṭ-* ‘bread’ and of the nominal class inflection *-i* for the feminine, as in (12b). As discussed for Romanian (8), we assume that the lexical base ‘bread’ has predicative content, and the nominal class (feminine) morphology *-i* provides a descriptive content for the argument of the predicative base (ultimately bound by an abstract D); we postulate no abstract case (section 1.2). The perfect participle *khadd-i* ‘eaten’ consists of the V root, *khadd-* and the *-i* inflection, which, we assume, provides a morphological level saturation for the internal argument of the verb, as in (12a).

- (12) a.  b.  Punjabi

In standard minimalist terms, Agree is responsible for matching the features of *roṭṭi* with the *-i* inflection of the verb in (11). The procedure is computational and is driven by the presence of uninterpretable phi-features on the verb, acting as probes for the interpretable phi-features of N/DP. We consider that uninterpretable features are a potentially unrestricted device. Their very lack of interpretation allows any uninterpretable feature to be associated with any category – nor do we accept Chomsky’s (1995) conclusion that they are empirically forced (see Manzini and Savoia 2007 on subject-verb agreement). Correspondingly, we call into question the role of uninterpretability in agreement, as a technical tool conceived to force derivation (Chomsky 1995), and therefore as an acquisition device (Biberauer 2014).

In present terms, the *-i* inflection has pronominal-like content, capable of contributing towards the satisfaction of the open argument slots of predicative bases, as in (13). Agreement is a byproduct of the fact that the elementary semantic content of both *-i* elements in (11) is bound by the same referential material, to be identified with the (abstract) D definite determiner of *roṭṭi*. The latter ultimately satisfies the internal theta-role both of the noun and of the verb. Note that (13) includes the TP layer as well, realized by the ‘be’ auxiliary, though as far as we can tell, the auxiliary does not determine either case or agreement. For the time being, the ergative external argument is missing from the structure.

The analysis of transitive sentences in (13) makes predictions on intransitive sentences. With verbs which on cross-linguistic grounds are unaccusative, i.e. take only an internal argument, this argument appears in the absolute form and agrees with the verb, as shown in (14a) – as expected on the basis of what happens to the internal argument in (13). By contrast, the sole argument of unergatives is introduced by ergative case, i.e. it behaves like the external argument of transitives, as in (14b). In the absence of an absolute argument, the perfect turns up in an invariable, non-agreeing form, confirming that the perfect inflection lexicalizes the internal argument.

- (14) a. su-i            degge-i  
 needle-Abs.fsg    fall.Perf-fsg  
 ‘A/the needle/the needles has/have fallen’
- b. kur-i-ne /    muṅḍ-e-ne            hass-ea            si  
 girl-fsg-Erg/boy-Obl.msg-Erg    laugh.Perf-msg    be.Past  
 ‘the girl/the boy laughed’
- Punjabi*

## 2.2. The progressive

The progressive participle agrees in person and number with the external argument of transitives, in the absolute form, as illustrated in (10b) above and here in (15).

- (15) o            muṅḍ-a            dekh-d-a/-i            (a)  
 s/he.Absboy-Abs.msg    see-Progr-msg/-fsg    be.Pres  
 ‘S/he is seeing a boy’
- Punjabi*

With unergatives and unaccusatives, the sole argument surfaces in the absolute form and agrees with the verb, as in (16). Therefore (15)–(16) taken together display the nominative alignment also seen in English or Romance.

- (16) a. kur-i            ron-d-i            (a)  
 girl-Abs.fsg    cry-Progr-fsg    be:Pres  
 ‘A/the girl is crying’

allows a further level of structure to be projected, namely AspP, and a further argument to be introduced as Spec of AspP, namely *o* ‘he’ in (18). This is interpreted as the external argument, i.e. as the argument (causer or other) applied to the elementary VP event, defined by the predicate and its internal argument. The phi-features inflection *-a* in turn composes not with the verb base V, but with the V-Asp complex – which means that it picks up the argument introduced by Asp, here the external argument (or the sole argument of intransitives in (16)). In the configuration so created, the *o* pronoun and the *-a* inflection therefore agree, which in present terms means that they concur to the lexicalization of the same argument slot of the predicate

### 2.3. The aspectual split

According to section 2.1, the perfect participle in languages like Punjabi is a VP predicate, essentially displaying the same internal complexity as an NP or AP predicate. By contrast, the progressive participle has a more complex internal configuration including an Asp head. In the progressive, therefore, transitivity is built into the structure by Asp – which means that both subject and object can be introduced as bare DPs, as we just saw in (18). Standard minimalism assumes a two-layered verbal structure where the internal argument is introduced by the V predicate, while the external argument is introduced by the transitivizing predicate *v*. For Punjabi we propose a categorial organization reflecting the overt morphological structuring of the language, so that the external argument is introduced by progressive Aspect, not by some more abstract *v* or Voice category. The absence of the Asp layer of structure that characterizes perfects according to present assumptions means that a causer/agent is not licensed by a functional projection of V and can only be introduced via an oblique case, namely the ergative to which we return in section 3.

As mentioned at the beginning of this section, we share the idea that ergative alignments corresponds to a more elementary organization of the predicate than nominative alignments with several recent generative works (Laka 2006, Coon 2013, Baker and Atlamaz 2013, Nash 2014). At the same time here the contrast between the various alignments is ascribed directly to the overt morphological constituency of the participles involved as they project to the syntax (VP vs. AspP). In present terms, progressive aspect introduces an eventive organization of the sentence, corresponding to the projection of a further Asp level of structure. On the contrary, the perfect denotes a property. Thus perfects introduce the internal argument of the predication; any additional argument, and specifically the external argument, can only be introduced as an oblique. In this respect we share the same outlook as Alexiadou (2001: 172-173) namely that “nominalizations and ergative patterns ... are reflections of the same structure: one that involves a single theme argument that appears as sister of the lexical root, and an adjunct type of phrase that introduces the agent”. Section 3 will be devoted to making the oblique characterization of the external argument more precise.

If the ergative case is connected to the dative (Butt and Ahmed 2011 and related literature), in present terms this is tantamount to connecting it to possession/inclusion. This leads us back to the stream of literature, both historical (Benveniste's 1966) and generative (Johns 1992, Alexiadou 2001), that connects 'ergative' structure with nominal possession structures – as briefly discussed in section 1.2. Suppose that this literature is substantially correct. We have already seen that the inclusion category ( $\sqsubseteq$ ) is externalized as *-de* (the conventional genitive) when embedded in DPs, as in (7b), and as *-nu* (the conventional dative) when embedded under VP, as in (7a).

We now are lead to conclude that the same ( $\sqsubseteq$ ) content characterizes *-ne*, i.e. the descriptive ergative, in perfects. Combining this characterization for ergative case with the structure of the perfect VP in (13), we obtain (21) as the structure for example (11). We again treat ( $\sqsubseteq$ ) as a predicate, with two argument places. Its internal argument, namely 's/he', to which ( $\sqsubseteq$ ) morphologically attaches, is interpreted as including (or locating etc.) not another DP, as in the genitive and dative contexts in (7), but rather a state/event, represented by the VP ('eaten the bread'), which is the second argument of ( $\sqsubseteq$ ).

In other words, identifying the ergative with the fundamental oblique relation ( $\sqsubseteq$ ) implies assuming that this relation may hold not only between two DPs but also between a DP and a predicate. The idea that an oblique head may relate two DPs, but also a DP and an event/state has precedents in the generative literature, specifically in the characterization of low and high Appls by Pylkkänen (2008). Low Appls, corresponding roughly to goal datives, introduce a relation between the goal DP and the theme DP; high Appls, corresponding for instance to experiencer datives, introduce a relation between the experiencer DP and the predicate. We apply the same idea to Differential Object Marking (DOM, Plank 1984, Aissen 2003), as illustrated below by Punjabi, where the DOM alignment is necessary if the internal argument of transitives is animate and definite (or at least one of the two), including of course pronouns.

In Punjabi, DOM is lexicalized by the same *-nu* inflection as the goal dative, as illustrated in (22a) for the progressive and in (22b) for the perfect. In the progressive (22a), the verb agrees with the external argument in the absolute form, as already illustrated in (18). In the perfect (22b), the DOM case on the internal argument determines lack of agreement between it and the participle (a point we shall come back to). Since the participle does not agree with the ergative external argument either, it surfaces in an invariable masculine singular form, as in (22).

- (22) a. mɛ:     muŋd̥-e-nu/ti-nnu             dekh-d-i     a  
 I.Abs(f) boy-Obl.msg-Obl/you-Obl     see-Progr-fsg   be.Pres  
 ‘I am seeing the boy/you’
- b. o-ne                   mi-nnu/ti-nnu             dekkh-ea  
 s/he-Erg               me-Obl/you-Obl           see.Perf-msg  
 ‘S/he saw me/you’
- Punjabi*

Though the DOM case is traditionally glossed as an accusative, its coincidence with the dative is not a matter of mere homophony. A syntactic argument in favour of its oblique status is provided precisely by the fact that it is incompatible with agreement in the perfect, as in (22b). Furthermore, the expression of DOM systematically coincides with that of the dative across the Indo-European languages, including Romance languages, Hindi, and many Iranian varieties. Manzini and Savoia (2014b), Manzini and Franco (to appear) therefore take the lexical coincidence with dative at face value and propose that DOM introduces a ( $\sqsubseteq$ ) relation between the animate/specific internal argument to which it attaches and the V elementary event. Consider structure (23) for sentence (22a). The deictic DP *ti*-‘you’ is attached to the core of the sentence by the ( $\sqsubseteq$ ) case, lexicalized by *-nu* – as if one were to say ‘I give/have (a) sight to/of you’ where the internal argument ‘you’ is in an abstract possessor/inclusion to the elementary state/event ‘see/sight’.<sup>5</sup>

- (23)
- 
- Punjabi*

Summarizing our core proposal, under the account of Punjabi resulting from the progressive structure in (18) and the perfect structure in (21), the same predicate-argument complex can be introduced by a two-layered predicate or by a one-layered predicate plus an oblique ‘case’ on one of the arguments (in reality an elementary part-whole predicate). Therefore even within the same language, the same argument-predicate complex can be conveyed by different syntactic configuration, supporting the idea that there isn’t a universal categorial template (e.g. v-V) whose pronunciation is the only possible dimension of variation.

<sup>5</sup> Other aspects of the syntax of Punjabi cannot be dealt with here, in particular the person split. In the perfect, 1<sup>st</sup>/2<sup>nd</sup> person (1/2P) external argument are found in the absolute form, rather than in the ergative case obligatory with 3<sup>rd</sup> person referents. On the face of it, the attachment of 1/2P in the structure takes place by simple argument application (via a lambda-operator). In other words, Participants denotation, anchored to the universe of discourse, seems to dispense with specialized means of attachment to the structure of the event.

#### 4. 'ERGATIVITY' IN KURDIISH

We can now go back to Kurmanji Kurdish briefly introduced in section 1.2 as characterized by a contrast between a nominative alignment in the present and an ergative one in the perfect. As we saw Kurmanji has a two-case declension opposing a nominative/absolute form to an oblique one. The latter lexicalizes the goal argument of ditransitives ('dative') in (5a), the possessor of nouns ('genitive') in (5b) and the external argument of transitives/sole argument of intransitives in the ergative alignment. Therefore it provides *prima facie* support for our central analysis, that ergative is essentially a (contextual) differentiation of the basic 'possessor' (inclusion/location) oblique of natural languages.

In the nominative alignment, seen in the present, the nominative/absolute form of the noun lexicalizes the external argument of transitive verbs, as in (24a), and the sole argument of intransitives, as in (24b). The verb agrees with this absolute argument in person and number. The internal argument of transitives in (24a) is in the oblique.

- (24) a.      εz      kurk-(æk-)i                      ja:      də-bin-Im  
           I.Nom   boy-(indef)-Obl                   Lkr.f    Progr-see-1sg  
           'I(f) am seeing the/a boy'
- b.      ʒənək              ja:      də-nəv-it  
           woman.Nom   Lkr.f    Progr-sleep-3sg  
           'The woman is sleeping' *Kurmanji Kurdish*

In the ergative alignment, seen in the past, the absolute form characterizes the internal argument of transitives as in (25a), and the sole argument of intransitives (both unaccusative and unergative), as in (25b), with which the verb agrees in person and number. The external argument of transitives in (25a) is lexicalized by the oblique.

- (25) a.      ʒənək-e              εz                      nəχoft-əm  
           woman-Obl    I.Nom                   cover.Perf-1sg  
           'The woman covered me'
- b.      tu                      nəvəst-i  
           you.Nom        sleep.perf-2sg  
           'You have slept/he has slept' *Kurmanji Kurdish*

We tentatively assume that the ergativity split of Kurmanji has the same basic shape as that of Punjabi.<sup>6</sup> We maintain that the organization of the predicate is simpler in the

<sup>6</sup> The forms of the verb in (24) and (25) are traditionally described as present and past. However the T category is too high in the sentence to be able to determine different internal shapes of the predicate. Therefore here we assume that the split is aspectual, opposing imperfective and perfective. It should be noted that there is an empirical difficulty with the identification of the past with a perfective, namely that it can combine with the *di-* prefix with progressive interpretation. Nevertheless, Thackston (2006) shows that *di-* is in complementary distribution with the subjunctive prefix *bi-* and with the negative prefix in the present, leading him to label *di-* as a 'modal prefix'. In structural terms, the interaction with negation and subjunctive morphology, which is external to the predicate (VP/AspP), supports the conclusion that the *di-* (*də-*) morphology is introduced when the basic shape of the predicate, either VP or AspP, is defined.

perfect, which in present terms corresponds to a VP. In the absence of an Asp layer, the external argument is introduced by the oblique case/elementary predicate ( $\underline{\subseteq}$ ), denoting a relation between the argument itself and the V(P) event, as in (26). The agreement on the verb targets the internal argument, which correspondingly surfaces in the absolute form.

In comparison with Punjabi, and differently from it, Kurmanji presents a classical ergative alignment, which opposes the external argument of transitives to other arguments (the internal argument of transitives and the sole argument of all intransitives); the alignment of Punjabi is what is more properly characterized as active/inactive. In practice, ergative and active alignment differ with respect to how they treat the sole argument of unergatives. We model Kurmanji unergatives by assuming that the verb inflection lexicalizes the first argument (internal or external) to be syntactically merged. The structure of the unergative sentence in (27), cf. example (25b), is similar to that of an unaccusative, since the sole argument of intransitives is the first syntactically merged argument.

Let us turn to imperfective sentences. If we apply to them the same analysis as for the Punjabi progressive, we obtain structures like (28) for the transitive example (24a). Assuming that the verb inflection composes with Asp, we expect that it will agree with the outer argument of the predicate, i.e. the external argument in a transitive or unergative structure or the internal argument if the verb is unaccusative. In this respect, therefore, Kurmanji poses no difficulty, replicating the pattern already studied for Punjabi.

A notable property of Kurmanji is that oblique case marking of the internal argument in structures like (28) is the only admissible option. Extending previous proposals on Punjabi DOM, the internal argument in (28) is attached through the ( $\subseteq$ ) case, as in (29).

The interpretation that we impute to the structure in (29) is the one already outlined for Punjabi DOM objects, in the sense that the internal argument is treated as a possessor of the predicate (included in) V. The alternative is to say that the oblique case in Kurmanji is the default case, as Baker and Atlamaz (2013) propose. However note that it is neither a morphological default (the morphological default is obviously the absolute form) – nor the semantic default (an empty feature matrix), since it can alone support the dative/genitive interpretation, as illustrated in section 1.1.

## 5. CONCLUSIONS

In the first part of this article we proposed that oblique complement cases, like dative and genitive, have a predicative content. Specifically they introduce an inclusion or part/whole relation whereby the DP they attach to is taken to include (hence possess) a local DP. We illustrated this point with data from Romanian. We link this analysis of obliques to the analysis of ergative alignments, in Punjabi and Kurdish. Our core conclusion with respect to the latter is that while progressive sentences have structures where the external argument is attached to an Asp verbal layer of structure, in perfect sentences the external argument is attached to the main sentential spine via the ergative case, in reality an elementary predicate denoting inclusion-of-the event. Perfects denote properties; therefore, while they introduce the internal argument of the predication, the external argument can only be introduced as an oblique, i.e. ultimately as a possessor, if we take ( $\subseteq$ ) to be the fundamental characterization of obliques. On the contrary, the progressive aspect introduces an eventive organization of the sentence, corresponding to the projection of an Asp level of structure. Given these assumptions, we predict the basic shape of the aspectual split, whereby the progressive presents a nominative-accusative alignment (i.e. two direct cases) – while the perfect presents the ergative alignment (an oblique and a direct case).
